Marijuana—December, 2011
An Update from the National Institute on Drug Abuse

Marijuana Abuse in the United States
In 2010, more than 29 million Americans (11.5%) aged 12 or older reported abusing marijuana within the past year—a significant increase over rates reported each year from 2002-2008. According to NIDA’s Monitoring the Future study of 8th, 10th, and 12th graders, a consistent decline in marijuana use began in the mid-1990’s and continued into the early 2000s. But in the past few years this trend has reversed with 5-year trends showing significant increases among 10th and 12th graders for daily, current and past year use. This year, 12.5% of 8th graders, 28.8% of 10th graders, and 36.4% of 12th graders reported past-year marijuana use. Although there were no increases between 2010 and 2011, it appears that marijuana use continues to exceed cigarette use in these students. In 2011, 22.6% of high school seniors used marijuana in the past 30 days compared with 18.7% who smoked cigarettes. This year’s survey captured the use of synthetic marijuana, also known as K2 or “Spice,” among high school seniors for the first time. Almost 1 in 9, or 11.4%, of high school seniors reported using Spice in the past year.

Marijuana’s Effects
Marijuana is derived from a plant containing more than 400 chemical constituents. Tetrahydrocannabinol (THC) is the main psychoactive ingredient in marijuana. It binds to cannabinoid (CB) receptors, widely distributed throughout the nervous system, and other parts of the body. In the brain, CB receptors are found in high concentrations in areas that influence pleasure, memory, thought, concentration, sensory and time perception, appetite, pain, and movement coordination. This is why marijuana can have wide ranging effects, including:

- Impaired short-term memory (memory of recent events)—making it hard to learn and retain information, particularly complex tasks.
- Slowed reaction time and impaired motor coordination—throwing off athletic performance, impairing driving skills, and increasing the risk of injuries
- Altered judgment and decisionmaking—possibly leading to high-risk sexual behaviors that could lead to the spread of sexually transmitted diseases.
- Increased heart rate by 20-100%—may increase the risk of heart attack, especially in otherwise vulnerable individuals
- Altered mood—euphoria, calmness, or in high doses, anxiety, paranoia

Exposure during critical developmental periods: From animal research, THC exposure pre- or perinatally or during adolescence can alter brain development, particularly in areas related to mood, reward, and executive function (e.g., cognitive flexibility).

Long-term marijuana abuse can lead to:
- Addiction
- Poorer educational outcomes and job performance, diminished life satisfaction
- Respiratory problems—chronic cough, bronchitis
- Risk of psychosis in vulnerable individuals
Marijuana and Mental Illness
People who are dependent on marijuana frequently have other comorbid mental disorders (see figure). Population studies reveal an association between cannabis use and increased risk of schizophrenia and, to a lesser extent, depression, and anxiety. There are now sufficient data indicating that marijuana may trigger the onset or relapse of schizophrenia in people predisposed to it, perhaps also intensifying their symptoms.

Marijuana and Addiction
Long-term marijuana use can lead to addiction; that is, people use the drug compulsively even though it interferes with family, school, work, and recreational activities. According to NSDUH, in 2010 of the estimated 7.1 million Americans classified with dependence on or abuse of illicit drugs, nearly 4.5 million were dependent on or abused marijuana. Research has shown that approximately 9% of people who use marijuana may become dependent. The risk of addiction goes up to about 1 in 6 among those who start using as adolescents, and 25-50% of daily users. In 2009, 18% of people entering drug abuse treatment programs reported marijuana as their primary drug of abuse (70% of those aged 12-14; and 72% of those 15-17), representing more than 350,000 admissions (TEDS, 2009). Along with craving, withdrawal symptoms such as irritability, sleeping problems, and anxiety can make it difficult for long-term marijuana smokers to quit.

Treatment for Marijuana Addiction
Behavioral interventions, including cognitive-behavioral therapy and motivational incentives (i.e., providing vouchers for goods or services to patients who remain abstinent) have shown moderate efficacy in treating marijuana dependence. Although no medications are currently available, recent discoveries about the workings of the cannabinoid system offer promise for the development of medications to ease withdrawal, block the intoxicating effects of marijuana, and prevent relapse.

Marijuana as Medicine
The potential medicinal properties of marijuana have been the subject of substantive research and heated debate. And while marijuana is not an FDA-approved medicine, 16 states and the District of Columbia have currently legalized its medical use. Scientists have confirmed that the cannabis plant contains active ingredients with therapeutic potential for relieving pain, controlling nausea, stimulating appetite, and decreasing ocular pressure. As a result, a 1999 Institute of Medicine report concluded that further research on cannabinoid drugs and safe delivery systems was warranted.

Marijuana itself is an unlikely medication candidate for several reasons: (1) it is an unpurified plant containing numerous chemicals with unknown health effects; (2) it is typically consumed by smoking, further contributing to potential adverse effects; and (3) its cognitive impairing effects may limit its utility. The promise lies instead in designing tailored medications, developed from marijuana’s active components, for specific conditions or symptoms with improved risk/benefit profiles. Scientists are actively engaged in this pursuit and hope to bring to market a new generation of safe and effective medications that avoid the adverse effects of smoked marijuana.
